Assuming that the deployment of one sensor has one unit cost, we define utilization efficiency as network lifetime  $L$  divided by the number of deployed sensors  $N$ , i.e.,  $\eta = L/N$ . Utilization efficiency indicates the rate at which network lifetime  $L$  increases with the network size  $N$ . It captures the tradeoff

Abstract: Wireless sensor networks (WSNs) have been widely used in a plenty of applications. To achieve higher efficiency for data collection, WSNs are often partitioned into several disjointed clusters, each with a representative cluster head in charge of the data gathering and routing process. Such a partition is balanced and effective, if the distance between
